General overview of the calibration site

Description

- Corsica has been chosen to be a semi-permanent calibration site for radar altimeters of present and future altimetric missions. It is composed of nearly 2 segments.
- Ajaccio:** a geodetic site for satellite tracking (SLR, DORIS). A permanent GPS station and a numeric tide gauge are planned to be installed in a next future
- Senetosia:** a tide gauges site located close to TOPEX/Poseidon ground track (N 08)

Brief History

- Sept. 1996 to Feb. 1997: Calibration experiment using French Transportable Laser Ranging System at Ajaccio and two tide gauges (one at Ajaccio and the other at Senetosia)
- May 1998: Installation of two other tide gauges at Senetosia. Geodetic operations (GPS, leveling, see Tables 1 and 2), GPS Buoys experiment for geoid slopes determination.

GPS Buoys Experiment

- Calibration results from the first campaign (1996-97) have shown that the geoid gradient in the Senetosia area should be very high. Then, it has been decided to improve this site by:
- Installing 2 other tide gauges in both sides of T/P ground tracks (see Figure 1).
- determining the geoid slopes using a GPS buoys technique. In order to compare the GPS receivers precision/accuracy, 3 GPS receivers type have been used: Turbo-rogue (JPL), Ashtech (IGN) and SERCEL (DSNP).

GPS Buoys experiment results

1- GPS Buoys Heights determination

Instantaneous GPS Heights

- GPS heights have been corrected from RINEX files of all the receivers using Ashtech Software (PRISM-PNAV Vers. 2.4). GPS orbits are from navigation message. Ionospheric correction from dual-frequency, and ambiguities solved.
- SERCEL data have also been processed using DSNP software (SPACK).
- Turbo-rogue data have also been processed using Gipsy/Oasis II (Webb and Zumberge, 1995). Rather than explicitly differencing the observations, GOALL uses for clocks of the participants (while noise resets with one reference clock fixed). In the first step, we use the ionospheric-constraint bias fixing technique (Blewitt et al., 1988), which does involve formation of double differences.

Filtered GPS Heights

- All GPS heights have been filtered using Vondrak filter (Vondrak, 1977), with a 60 second period. It means that all signals with period higher than 60 s are kept. An example of filtered data is given in Figure 4.
- GPS heights from GOALL software (Turbo-rogue data) have also been filtered by a boxcar filter of 60 s.

Figure 4. GPS heights from SERCEL data. Red lines correspond to filtered heights using Vondrak filter.

Comparisons

- All GPS heights (filtered or not) have been compared for common sessions (different receivers).
- Comparisons of software solutions have also been performed. Results are given in Table 3. An example of differences between common sessions and 2 different receivers is presented in Figure 5.

Table 3. GPS height differences (mean values) over an entire session

Figure 5. Differences between Turbo-rogue and Ashtech GPS heights on the 05/10/98 session.

2- Tides correction for GPS Buoys Heights

- The GPS heights have been corrected from tides variations using mean tides variations computed with the three tide gauges (M, M, and M), see Tables 5 and 6). An independent determination has been performed by B. Haines with Turbo-rogue data (GPS heights, filter, tide correction): differences are presented in Table 4.
- The tide gauges time series are illustrated in Figure 6.
- An example of this correction is given in Figure 7.

Figure 6. Tide gauges height time series.

Figure 7. Tide correction for 2 GPS sessions. Red lines for corrected heights.

3- Comparisons with Tide gauges

- Differences between GPS heights and tide gauges heights have been computed at each GPS data using linear interpolation between tide gauges data. Results of the average differences for all receivers at each tide gauges location are given in Table 7. Figure 8 gives an example of such differences for M, tide gauge.
- Figure 9 shows GPS heights and M, tide gauges data for a GPS session.
