# Wave transformation in current

- Significant swell height and dominant direction

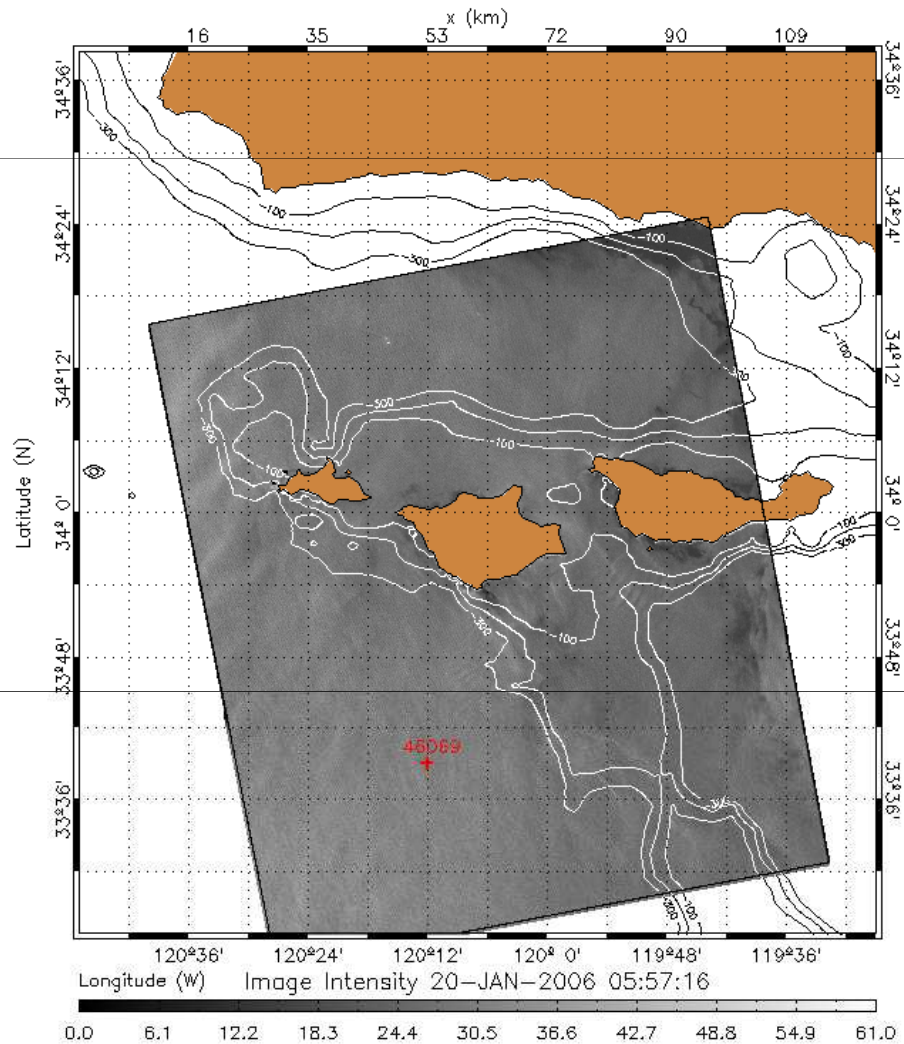

# SAR swell products

- Only SAR enables observation of spatial variations of 2D swell spectrum measurement
  - <http://soprano.cls.fr/waveProducts/>
- Available information of the swell component
  - Significant wave height
  - Wavelength (size of arrow)
  - Dominant direction
- General breakthrough
  - First high resolution wave field observation at 5km resolution
  - Wave inversion in shallow water

# Observation of Swell variation in coastal area

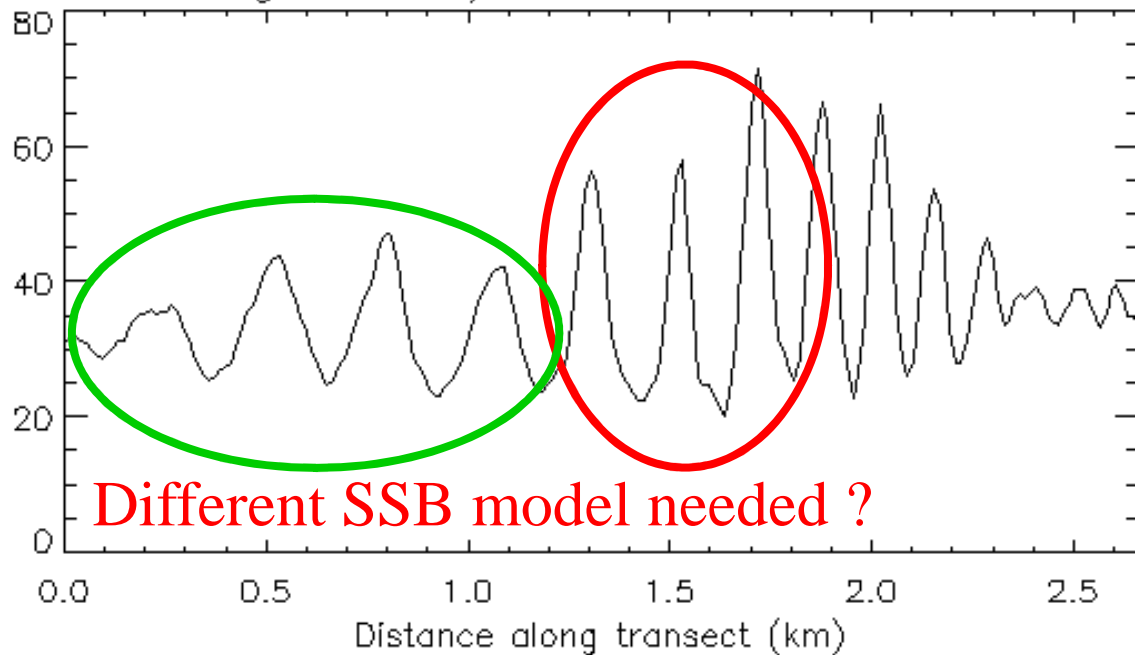

# Swell nonlinearities in shallow water

Image Intensity 15-NOV-2001 17:52:36

# Infragravity waves and Sea level remote sensing

## Generalities on infragravity (IG) waves

1. Unlike gravity waves, free IG waves are typically longer than altimeter footprints

2. Infragravity (IG) waves are generated as « bound waves » by the nonlinear difference interaction of « normal waves » of frequencies  $f_1$  and  $f_2$  and wavenumbers  $k_1$  and  $k_2$ :

$$f_{IG} = f_1 - f_2 \quad (0.001 \text{ to } 0.05 \text{ Hz})$$

$$\text{and } k_{IG} = k_1 - k_2$$

At this stage the wavelength of IG waves is the length of wave groups (0 (1 km)).

Forced IGs are strongly amplified at the coast (amplitude can reach 1 m on the beach face).

As the forcing wave groups are dissipated, the IG waves are released as free modes. This energy is mostly trapped in the coastal zone, but a fraction of that energy leaks into the deep ocean. Free waves have the same frequency (0.001 to 0.05 Hz) ... but the wavelength is given by the linear surface gravity wave dispersion:

assuming shallow water:  $L_{IG} = \sqrt{g \cdot D} / f_{IG}$  [ more generally,  $f^2 = g k \tanh(kD) / (2\pi)^2$  ]

For  $D = 4000$  m and a typical  $f_{IG} = 0.02$  Hz, this gives  $L_{IG} = 9$  km

# Conclusion

- 1cm at 10km resolution shall necessitate validation with improved MDT and instantaneous surface current field at finer resolution
- Strong heterogeneity of wave field in dynamical area. Needs to estimate the impact on altimeter interferometric measurement precision
- Wave bends as function of vorticity (and the wave group velocity) : wave impact and high resolution topography anomalies like SSB are not independant of surface currents.
- SAR can provide an independant high resolution NRCS and Doppler shift map : when defining the orbit, having SWOT swath inside an existing SAR swath would bring interesting comparisons opportunities.
